

An analysis of learner arguments in a collective learning environment

Patrick Jermann, Pierre Dillenbourg

TECFA, University of Geneva, Switzerland

Abstract: This paper analyses the arguments of students in a learning activity entitled “Argue Graph”. This activity is intended to make students understand the relationship between learning theories and design choices in courseware development. The analysis of arguments is centered on the effects of discussion and opinion conflict on the elaboration of arguments. We then use an adaptation of a collective intelligence model to describe the knowledge flow among people and artifacts during the learning activity. Finally, the representations produced by the system, used by students to write a synthesis and by the teacher to debrief the class are analysed in relation to metacognition. We propose to consider these representations as metacognitive tools which structure the learning activity.

Keywords: constructivism, distributed intelligence, shared knowledge

Introduction

The recently started TECFA virtual campus relies on design principles drawn from our five-years experience in teaching a master degree in educational technology with Internet. Its organisation combines distance with presential periods: students attend courses for one week at the University and then work remotely for 5 to 7 weeks using a combination of available media (e-mail, discussion groups, MOOs, phone,...).

Among the characteristics of a virtual campus, the presence of learning activities which mediate and organise the access of students to resources is particularly important to us. We try to follow constructivist principles by providing the students with the opportunity to process/produce the knowledge to be acquired instead of simply absorbing it. Although the activities in the TECFA virtual campus rely on Internet tools, they concern both distance teaching and presential interactions.

Designing learning activities is relatively easy when the learning goal is an activity itself. For instance, we teach our students how to program with Authorware by asking them to go through a large set of programming exercises. However, when acquiring declarative knowledge (principles, theories, laws, concepts,...) the learning task cannot simply be derived from the task to be mastered.

Therefore we have implemented several learning activities to support the acquisition of declarative knowledge. They follow a similar scenario: students first complete a task not directly related to the target knowledge to be acquired. While they do so, the system records their activity and then produces a synthetic graphical representation of their performance. Finally, the teacher uses this representation to debrief the class. He turns students' experiential knowledge into academic knowledge by putting labels on new concepts and by structuring the outcome. We introduced the notion of pseudo-task to refer to a task which is not the skill to be mastered, but which produces learning by experience. The synthesis provided by the system represents the students as a collectivity. “Collective” differs from “collaborative” due to the fact that it does not

necessarily imply rich interactions among students. Simply, the system collects individual productions or data and makes them available for the whole group. Collective representations bring the social plane into the frame of reference used during the debriefing session. (Jermann & Dillenbourg, 1999).

This paper concerns a learning activity entitled “Argue Graph”. We first describe the steps which compose it. We then propose an analysis of arguments produced by students during the activity. In the discussion, we use an adaptation of a collective intelligence model (Smith, 1994) to describe the knowledge flow among people and artifacts during the learning activity. We will finally have a closer look at the representations produced by the system, used by students to write a synthesis and by the teacher to debrief the class.

Description of the “Argue Graph” activity

The goal of the “Argue Graph” activity is to make students understand the relationship between learning theories (e.g. constructivism, behaviorism,...) and design choices in courseware development.

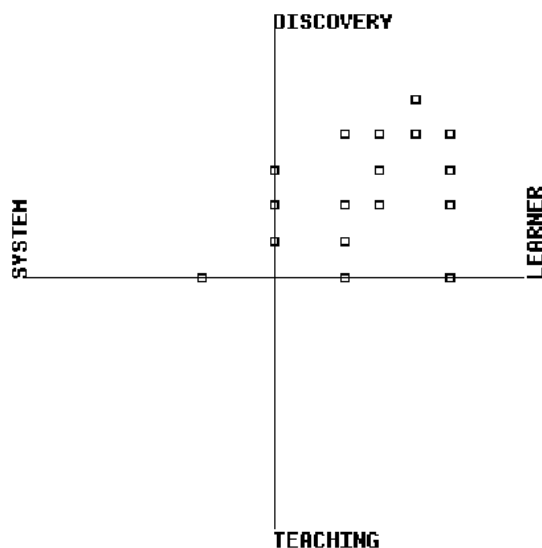

Figure 1: Scatterplot of individual answers. Each square corresponds to a student’s opinion. The horizontal axis opposes system vs. learner driven interaction. The vertical axis opposes discovery based learning vs. teaching. Names of students have been removed from the graph for confidentiality.

The scenario consists of six steps:

1. Students fill in a questionnaire concrete design choices in courseware development. Questions measure opinions, for example: “In a courseware, when a student makes an error, it is better to: a) Tell the student he made a mistake and give him the correct answer. b) Tell the student he made a mistake and give him an indication towards the correct answer. c) Show the student a blinking icon which allows him to ask the tutor for help. d) Give the student some time to find out the mistake by himself”. Students have to provide a short written argument for each of their choices.

2. The choices made at step 1 are then transformed into two scores reflecting whether students privilege system- vs. user-driven interactions on the one hand and a discovery vs. teaching based pedagogy on the other hand. The system draws a scatter plot on the basis of these scores and represents each student's position (Figure 1).
3. Pairs are formed so as to maximise differences within a pair according to the answers the students gave to the individual questionnaire at step 1. Students fill in the same questionnaire in pairs. While filling in the questionnaire, the students see the arguments both of them gave to support their answers in the individual phase. They have to agree on a common answer and provide a common argument.
4. The system produces a synthesis and a scatterplot representing the "migration" of each student from his initial position to the common position. The synthesis lists the individual and common arguments given for each question and draws a pie chart with the distribution of answers. Finally, a brief statement presents the relationship between underlying theories and the options the students can select in a question.
5. During this debriefing phase, the teacher reviews all arguments produced by individuals and pairs and articulates them with respect to the various theoretical frameworks in the domain.
6. Finally, students get some homework. They have to analyse the answers to one of the questions including thereby theoretical stakes and their own opinion.

This activity takes 4 hours to complete.

Research question

Intuitively, this activity works very well, as indicated by the high degree of learner involvement during all phases. However, the tool was not subject to a formal evaluation procedure. Nevertheless, we collected all answers and arguments in order to grasp learning mechanisms. Namely, we investigate the differences between individual answers and pairs answers.

Subjects

We ran two pre-experiments, with 15 students in 1997 and 17 students in 1998 respectively, after which the system was improved with regard to various functionalities. The experiment reported here was run on October 22nd 1998 with 18 students. Most students were located in the same quarter of the graph (Figure 1). This phenomenon is probably due to the fact that the questions did too clearly reflect the pedagogical values sponsored at TECFA and did not take into account the technical or financial dimensions of courseware development.

Variables

From now on we will designate the first time students answer as 'solo' condition and the second time as 'duo' condition. Since students answer twice to the same questionnaire, we have the opportunity to examine what differentiates answers given alone and in pairs. In these experiments, subjects seat next to each other in front of the machine. We did not record their discussion (this will be done in the next experiment). Hence, the analysis is restricted to their answers, i.e. the options selected and the arguments introduced into the system to justify this choice. We describe these answers with five variables:

Frequency of conflict:

The pairing method used in Step 3 aimed to create conflictual situations, i.e. make pairs answer a question to which individuals gave different answers. Hence, our first variable was the actual frequency of conflict, i.e. the number of times pair members had given different individual answers in solo.

Type of argument (solo and duo):

Accept: the argument provided supports the option selected, e.g. “I choose option 2 because it makes the learner autonomous”.

Discard: the argument rejects another option, e.g. “I choose option 2 because option 3 is too heavy to implement”.

Condition: the argument states some conditions for the option selected, e.g. “I choose option 2 if the learner is very young”.

Style of argument (solo and duo):

Justification: the argument contains at least one idea not present in the phrasing of the selected option.

Reformulation: the argument does not contain an idea not present in the selected option.

Semantic relation between solo arguments and duo argument:

Union: the duo argument contains the ideas stated by both solo arguments.

Victory: the duo argument contains the ideas of one of the solo arguments.

New: the duo argument contains an idea which is not present in either solo arguments.

Syntactic relation between solo arguments and duo argument:

Union: the duo argument contains words coming from both solo arguments.

Victory: the duo argument contains words taken from one of the solo arguments.

New: the duo argument contains words not present in either solo arguments.

Table 1 illustrates the usage of this coding scheme for the solo and duo answers of one pair at question 1. Questions 1 is:

In a courseware, when a student makes an error, it is better to:

1. Tell the student he made a mistake and give him the correct answer.
2. Tell the student he made a mistake and give him an indication towards the correct answer.
3. Show the student a blinking icon which allows him to ask the tutor for help.
4. Give the student some time to find out the mistake by himself’

Table 1: Coding example

Conflict	Option		Argument (we translate)	Code	
	2	SOLO 1	If he is directly given the correct answer, he might not remember it, if we don't say anything, he might not be aware of his error... The help icon is certainly a good solution, if one can see clearly that it gives help and that it appears only on errors.	D1J + D4J + C3J	
	3	SOLO 2	Trade-off between paternalism and neo liberalism	A3J	
YES	3	DUO	It allows him to ask for help when he needs it.	A3J	New Content New Syntax

The first solo argument (SOLO1) shows a combination of several types of arguments: options 1 and 4 are discarded and option 3 is accepted conditionally. Notice that option 2, which is the actual choice of the student, is not addressed explicitly by the corresponding argument. Arguments with this level of complexity are quite rare, for most of the arguments were coded with a single type and style, like it is the case for the second solo argument (SOLO2). All three arguments were considered as 'Justifications' because they contain new ideas with regard to the option stated in the question. The duo argument is 'New' with respect to the content, because it introduces the idea of the learner's autonomy which was not stated as such in the solo arguments. Syntactically, the duo argument is also 'New' because the words used to express the argument did not appear in the solo arguments.

Results

The system collected 180 solo answers and 90 duo answers to the questionnaire respectively. Some answers were incomplete, for instance when a student made a choice without providing an argument. The valid cases remaining for the analysis are 166 solo arguments and 67 duo arguments. The arguments were coded once by the two authors of this article and we did not use a second judge to validate the coding. Yet, most of the coding was straightforward.

Conflicts does occur

For 52% of the duo answers there was a conflict between the two solos answers. In other words, the method used to form pairs was rather effective. There is some relation between the distance in the graph and the frequency of conflict (the five pairs with a distance of 1 have a disagreement rate of 38%, while the pairs with a larger distance have a disagreement rate of 52.5%), but the size of the sample is not sufficient to compute a correlation rate.

These situations are of particular interest with respect to collaborative interaction because they enable socio-cognitive conflict (Doise & Mugny, 1981): a social conflict (having a different perspective) has to be solved through a cognitive coordination of the points of view. However,

further studies showed that conflict is neither a necessary, nor a sufficient condition for cognitive change. Beyond the intensity of conflict, it is the verbalisation necessary to solve the conflict which seems related to learning effects (Blaye, 1988; Butterworth, 1982). The effects of verbalisation is confirmed by the work on reciprocal teaching (Brown & Palincsar, 1989) and on self-explanation (Chi & al.,1989).

The type of arguments varies between solo and duo conditions

Table 2 presents types of arguments for the solo and duo conditions. We computed three proportion tests to compare the solo and duo conditions. The proportion of ‘Accept’ arguments is similar in both conditions even if significantly higher in the solo condition ($p < .05$). It appears that the proportion of ‘Discard’ arguments in the solo phase is higher than in the duo phase ($p < .05$). The proportion of ‘Condition’ arguments is higher in the duo phase than it is in the solo phase ($p < .05$). We will comment on the ‘Condition’ arguments when examining the effect of conflict on duo arguments.

Table 2: Type of arguments across Solo and Duo conditions

		Solo	%	Duo	%	Solo-Duo	<i>u</i>
Type of argument	Accept	136	82	51	76	0.06	0.048
	Condition	8	5	12	18	0.13	0.034
	Discard	22	13	4	6	0.07	0.037
		166	100	67	100		

The style of arguments varies between solo and duo conditions

Table 3 presents styles of arguments for the solo and duo conditions. The proportion of ‘Reformulation’ is very high in the solo phase (more than half of the answers are simple reformulations of the choices proposed in the question). This proportion is much lower in the duo phase ($p < .05$). We interpret this difference as follows. When answering alone, students had no reason to make the effort to justify their choice with an elaborated argument even if they elaborated one in their head. In pairs, the discussion which was necessary to agree on an argument seems to force students to make it explicit and to elaborate it. This interesting observation confirms the usefulness of this method. The difference could however also be due to the fact that student feel obliged to produce a more elaborated answer when they answer for the second time to the same question.

Table 3: Style of arguments across Solo and Duo conditions

		Solo	%	Duo	%	Solo-Duo	<i>u</i>
Style of argument	Justification	72	43	57	85	0.42	0.059

	Reformulation	94	57	10	15	0.42	0.060
		166	100	67	100		

The type of duo arguments varies according to conflict

Let us now look at the duo arguments. Since we designed the learning activity in order to create conflicts, we will center the analysis around this variable to see if it has an influence on the type and style of arguments.

Overall, there is not one student who wins all conflicts to the detriment of his colleague. For each AB pair, we counted the number of times that AB's duo answer corresponded A's previous solo answer versus the times it corresponded to B's previous solo answer. We thereby observed that pairs were rather symmetrical, the difference ranging between 0 and 2, with the exception of 2 pairs.

Table 4 presents the type of duo arguments for situations with and without conflict. In both cases 'Accept' arguments are predominant, students give an argument which directly supports their common choice. 'Condition' arguments are interesting because they violate the instructions given to the students: they were asked to choose only one possible option and to give an argument supporting it. This way of proceeding would correspond to the production of 'Accept' arguments. Paradoxically, the 'Condition' arguments match the underlying pedagogical goals of the activity better than the 'Accept' type. We want to show the students that there is not one correct theory in courseware design but that each design choice depends on specific contextual features.

All but one 'Condition' arguments were given in a conflictual situation where students have to defend their choice against another's opinions. This type of argument is a way to solve the conflict by complexifying the argument. Indeed, establishing 'if..then..else' constructions allows to make concessions to the loser of the conflict.

Unfortunately 2 cells (33.3%) from table 4 have expected count less than 5 so we cannot compute a reliable Chi-square test to validate these observation. Nevertheless, we will modify the instructions given for the production of arguments and plan to implement a semi-structured interface which fosters the production of 'Condition' arguments.

Table 4: Conflict and type of arguments

		Duo type of argument			Total
		Accept	Condition	Discard	
Conflict	NO	28	1	3	32
	YES	23	11	1	35
Total		51	12	4	67

The semantic relation between solo and duo arguments varies according to conflict

The semantic relation between solo and duo arguments is related to conflict as can be seen in Table 5. When there is no conflict, students often take the arguments they gave in the solo phase and put them together to produce a 'Union' argument. The production of a 'Victory' argument corresponds to the pair choosing one of the two arguments and use it as duo argument.

When there is a conflict between the choices students made in the solo phase, the 'New' and 'Victory' arguments are more numerous. A 'Victory' in this context corresponds to one student winning the conflict on both aspects of the answer: the choice and the argument. The production of 'New' arguments can be understood as a way to handle the conflict. Even if the choice of one student is taken by the pair, the 'New' argument has no relation with previous solo arguments. It is worth noticing that 9 out of 12 'Condition' arguments given in the duo phase are at the same time 'New' arguments.

Table 5: Conflict and Semantic relation between solo arguments and duo argument

$(\chi^2 = 6.136, p = .047)$		Relation between solo and duo arguments			
		New	Union	Victory	Total
Conflict	NO	6	16	10	32
	YES	14	8	13	35
Total		20	24	23	67

Discussion

Answering together to the questionnaire had an impact on the style of arguments (Reformulation vs. Justification) produced by the students. The duo arguments are more elaborated than the solo arguments. We propose that the reason for this change is that students make their opinions explicit and thereby more elaborated during the discussion. The type of arguments (Accept vs. Discard vs. Condition) also varies across solo and duo conditions. 'Discard' arguments are more frequent in the solo condition while 'Condition' arguments are more frequent in the duo condition.

In the duo condition, half of the cases are conflictual, i.e. students did not make the same choice in the solo condition. 'Condition' arguments appear mostly in a conflictual situation. There is also an increased production of semantically 'New' arguments. We have interpreted the production of this kind of arguments as resulting from a strategy intended to solve the conflict more fairly than by a 'Victory' of one of the students. It also indicates that students produce knowledge and explore the domain.

Up to here we analysed two steps from the scenario. We now propose to broaden the analysis by using a distributed cognition approach. The central idea of the distributed cognition approach is that our object of investigation is no more restricted to 'knowledge in the head' as it was the case in traditional cognitive science, but includes several agents and the artifacts they use to mediate their activity. Authors like Hutchins (1995) and Smith (1994) analysed the ongoing activity in a system by observing the knowledge flow among different artifacts. As Nardi (1996) points out,

there is also a particular interest in the analysis of external and internal representations and of the transformations they undergo when travelling through the system.

Figure 2: Knowledge flow and types in the Argue-Graph learning activity, adapted from Smith (1994). P=Private; S=Shared; I=Instrumental; T=Target. Numbers represent steps in the activity.

We will now describe the learning activity presented above from two viewpoints. First as a knowledge flow and then by focussing on the external representations it contains.

Knowledge flow model

In his book, Smith (1994) proposes a model of collective intelligence restricted to collaborative groups of 3 to 30 individuals working together for a long period of time to build an intellectual product. He presents a knowledge typology based on the information's persistence of display, i.e. how long knowledge can be viewed on a particular medium (See also Dillenbourg & al., 1997). Tangible knowledge is persistent and manipulated by individuals. It comprises the final product (called 'target product') and 'instrumental products' which support the group's work on the target but are not part of it. Intangible knowledge is not physically accessible and constitutes the shared and private knowledge people have in mind. Ephemeral products which temporarily take a physical form lie between these two types of knowledge. These allow the transformation of knowledge from one type into the other by the contributions of several members of the group. A semi-persistent media is associated to this type of knowledge. We now attempt to use the same terminology to describe the transformations the knowledge undergoes in the learning activity described above.

During steps 1 and 2, private intangible knowledge becomes shared through the mediation of an ephemeral representation. According to Smith's model, ephemeral knowledge is built by the people themselves. In our case, the system produces a collective representation of the individuals' opinions (Figure 1). Since this representation is accessible to everyone, their preconceptions are already shared to some extent. Students don't know the detailed opinions of each of their colleagues but they get an overview of the diversity of opinions. We have labelled this collective representation with the term 'social'.

In step 3, the passage between private and shared knowledge is more fine grained than in step 1 and 2 because two students have to explicitly and discuss their specific choices. There is no physical intermediate representation mediating the transformation of private to shared knowledge. But the questionnaire the students fill in contains the answers and arguments they gave at step 1 and they can rely on these informations to structure their discussion. Smith's model does not include collaborative interactions between two persons. According to Smith's typology the knowledge produced during the argumentative process is not observable and should be labelled intangible. Nevertheless, we propose to add an inter-individual ephemeral knowledge type to refer to the process of discussion, which mediates the passage between private and shared knowledge.

Step 4 consists in an instrumental representation. It is persistent and will be used to produce target knowledge. It shows all the arguments and the answers to the questionnaire in a tangible manner accessible to everyone.

Step 5 transforms the instrumental knowledge into private intangible knowledge. The teacher uses the instrumental knowledge produced by the system in step 4 to debrief the class. He reorganises the arguments and puts 'scientific' labels on them.

Step 6 is individual and transforms intangible private knowledge students have acquired during the debriefing into tangible target knowledge: students have to choose one of the questions from step 1 and write a short synthesis containing related theoretical stakes and their personal opinion. Students intensively used the instrumental knowledge from step 4 to compose their synthesis.

It appears in the model we just described that the knowledge to be acquired stems from a construction where students take an active role. Most of the arguments in favour or against the learning theories appear in the answers given by the students. Knowledge is mediated by various artefacts like graphs, discussions, syntheses. The level of interaction between people also varies from dyadic argumentation to group discussion during the debriefing. Can we deduce that the richer the environment and the interactions it supports, the better the learning? It is certainly not this trivial but the redundancy of information (Hutchins, 1991) may play a positive role in knowledge acquisition.

Collective representations as a support for learning

Nickerson (1993) addresses the question whether a group of people have metaknowledge. Metacognition has multiple meanings, ranging from the knowledge an individual has of his own mental activity to action regulation and control processes, for instance planification of the activity, supervision of the effects of actions. Finally, metacognition also comprises conception an intuitions the subjects has about the situation he's in (Schoenfeld, 1987).

We used Nickerson's hypothesis on group metacognition as a starting point for the design of three pedagogical scenarios with the common goal to acquire declarative knowledge. The "Argue

Graph” activity described in the beginning of this paper is one of those. The two other activities also use representations of students’ performance in a pseudo-task. In the “ergonomics laboratory” a bar chart illustrates measures of students’ performance when using the six interfaces (number of errors, time,...). In the “Multiple choice questionnaires defects” activity, a scatter plot illustrates the mismatch between the students’ self-evaluation of their competence in a domain and the real scores they get. A detailed description of these activities can be found in Jermann & Dillenbourg (1999).

The collective representations we described present various aspects of differentiation (either between interfaces or between self-evaluation and score or between opinions). We have interpreted the efforts to understand the differences that appear in the representation of performances as being a major source of learning in a previous contribution (Jermann & Dillenbourg, op. cit.).

These collective representations and syntheses give a trace of the group activity. In some cases, when the students’ names appear, they can deduce information about their own behaviour from the representation. When this is not the case, they get a global image of the group. It is not clear though if knowledge like ‘we have different opinions’, ‘we all make the same mistakes’, ‘we all overestimated our competence’ or ‘I am an extremist’, ‘I succeeded better than my colleagues’ have the same impact. We saw that students were fond of representations where they could see their own position and it seems that the comparison with others is strongly motivating.

From a metacognitive viewpoint, the representations are used as tools which guide and motivate the construction of knowledge. Students take over the knowledge by interpreting the graphs and data they get.

Conclusion

This paper presented an analysis of arguments produced by students in a learning activity entitled “Argue Graph” where students twice answer to a questionnaire, a first time alone and then in pairs. We observed that answering in pairs had a positive impact on the elaboration of arguments provided to justify the choices in the questionnaire. We interpreted the improvement of arguments as stemming from the discussion necessary to give a common answer. Students make their opinions explicit and thereby more elaborated during the discussion. We then used a distributed cognition approach to analyse the “Argue Graph” learning activity. Smith’s (1994) model of collective intelligence allowed us to describe the transformations knowledge undergoes during the learning process. Following Nickerson (1993) we addressed the question of collective metacognition and proposed to consider collective representations as tools which guide the knowledge acquisition.

Acknowledgments

TECFA Virtual Campus has been developed with the help of Cyril Roiron and Jean-Christophe Brouze for the activities mentioned here, and more generally with the collaboration of David Ott, Daniel Schneider, Daniel Peraya, Patrick Mendelsohn, Philippe Lemay and Didier Strasser.
